

# Operating Systems

## 22. Authentication

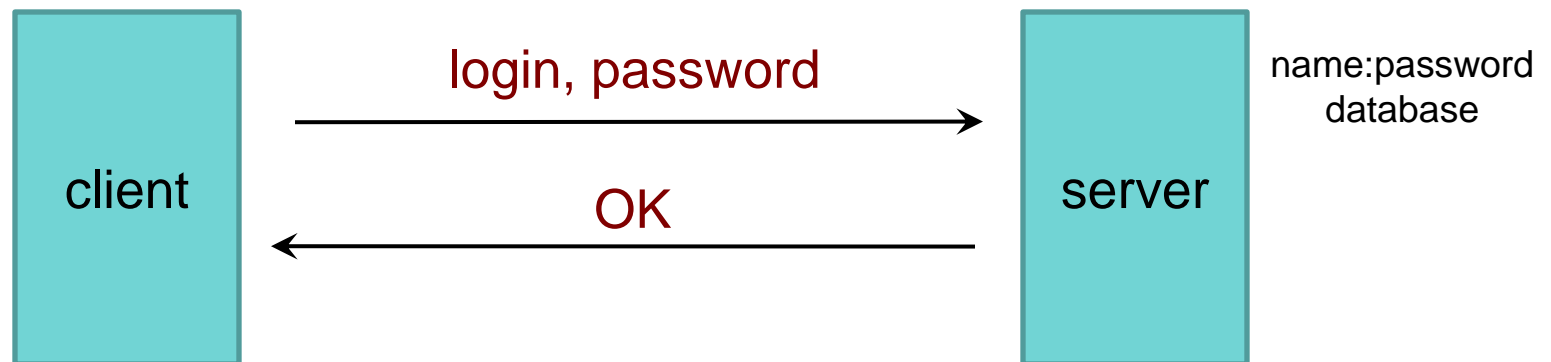

Paul Krzyzanowski

Rutgers University

Spring 2015

# Authentication: PAP

## Password Authentication Protocol

- Unencrypted, reusable passwords
- Insecure on an open network
- Also, password file must be protected from open access
  - But administrators can still see everyone's passwords

# PAP: Reusable passwords

Problem: Open access to the password file

What if the password file isn't sufficiently protected and an intruder gets hold of it? All passwords are now compromised!

Even if a trusted admin sees your password, this might also be your password on other systems.

**Solution:**

Store a **hash** of the password in a file

- Given a file, you don't get the passwords
- Have to resort to a **dictionary** or **brute-force attack**
- Example, passwords hashed with SHA-512 hashes (SHA-2)

# What is a dictionary attack?

## November 2013 – Adobe security breach

- 152 million Adobe customer records ... with encrypted passwords
- Adobe encrypted passwords with a symmetric key algorithm
- ... and used the same key for every password!

### Top 26 Adobe Passwords

	Frequency	Password
1	1,911,938	123456
2	446,162	123456789
3	345,834	password
4	211,659	adobe123
5	201,580	12345678
6	130,832	qwerty
7	124,253	1234567
8	113,884	111111
9	83,411	photoshop
10	82,694	123123
11	76,910	1234567890
12	76,186	000000
13	70,791	abc123

	Frequency	Password
14	61,453	1234
15	56,744	adobe1
16	54,651	macromedia
17	48,850	azerty
18	47,142	iloveyou
19	44,281	aaaaaa
20	43,670	654321
21	43,497	12345
22	37,407	666666
23	35,325	sunshine
24	34,963	123321
25	33,452	letmein
26	32,549	monkey

# What is a dictionary attack?

- **Suppose you got access to a list of hashed passwords**
- **Brute-force, exhaustive search: try every combination**
  - Letters (A-Z, a-z), numbers (0-9), symbols (!@#\$%...)
  - Assume 30 symbols + 52 letters + 10 digits = 92 characters
  - Test all passwords up to length 8
  - Combinations =  $92^8 + 92^7 + 92^6 + 92^5 + 92^4 + 92^3 + 92^2 + 92^1 = 5.189 \times 10^{15}$
  - If we test 1 billion passwords per second:  $\approx 60$  days
- **But some passwords are more likely than others**
  - 1,991,938 Adobe customers used a password = “123456”
  - 345,834 users used a password = “password”
- **Dictionary attack**
  - Test lists of common passwords, dictionary words, names
  - Add common substitutions, prefixes, and suffixes

# What is salt?

- How to speed up a dictionary attack
  - Create a table of **precomputed hashes**
  - Now we just search a table

Example: SHA-512 hash of “password” =  
sQnzu7wkTrgkQZF+0G1hi5Al3Qmzv0bXgc5THBqi7mAsdd4XIl27ASbRt  
9fEyavWi6m0QP9B8IThf+rDKy8hg==

- **Salt** = random string (typically up to 16 characters)
  - Concatenated with the password
  - Stored with the password file (it’s not secret)
  - Even if you know the salt, you cannot use precomputed hashes to search for a password (because the salt is prefixed)

Example: SHA-512 hash of “am\$7b22QLpassword”, salt = “am\$7b22QL”:  
ntlXjDMnueMWig4dtWoMbaguucW6xV6cHJ+7yNrGvdoyFFRVb/LLqS01/pXS  
8xZ+ur7zPO2yn88xcliUPQj7xg==

- You will not have a precomputed hash of “am\$7b22QLpassword” !

# PAP: Reusable passwords

## Problem #2: Network sniffing

Passwords can be stolen by observing a user's session in person or over a network:

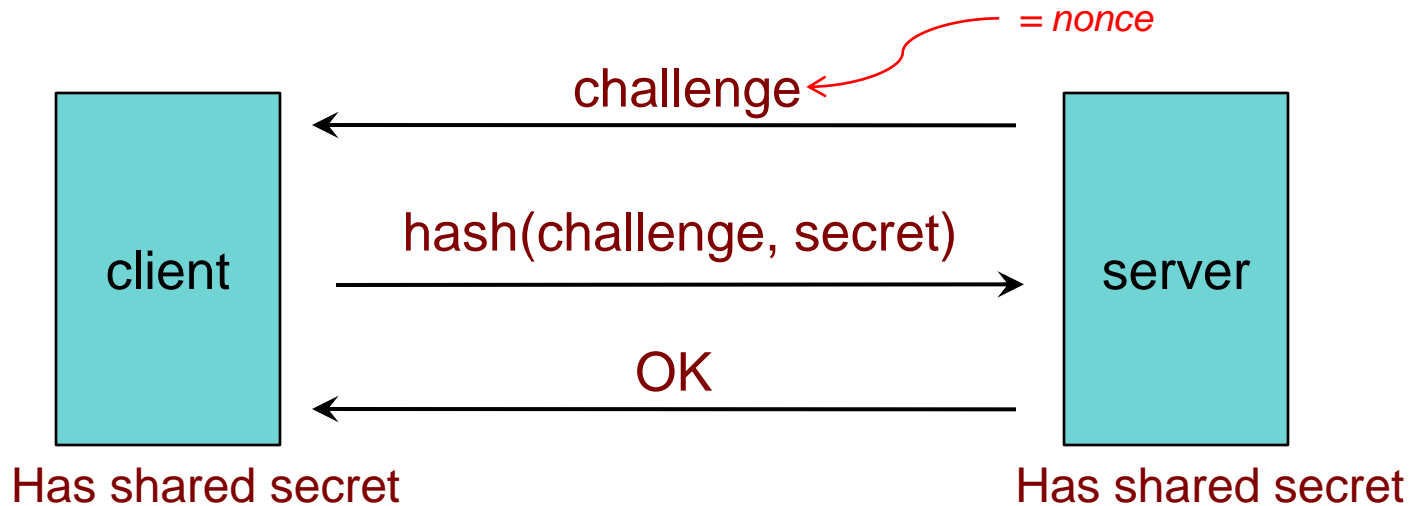

- snoop on telnet, ftp, rlogin, rsh sessions
- Trojan horse
- social engineering
- brute-force or dictionary attacks

## Solutions:

- (1) Use **one-time passwords**
- (2) Use an encrypted communication channel

# Authentication: CHAP

## Challenge-Handshake Authentication Protocol

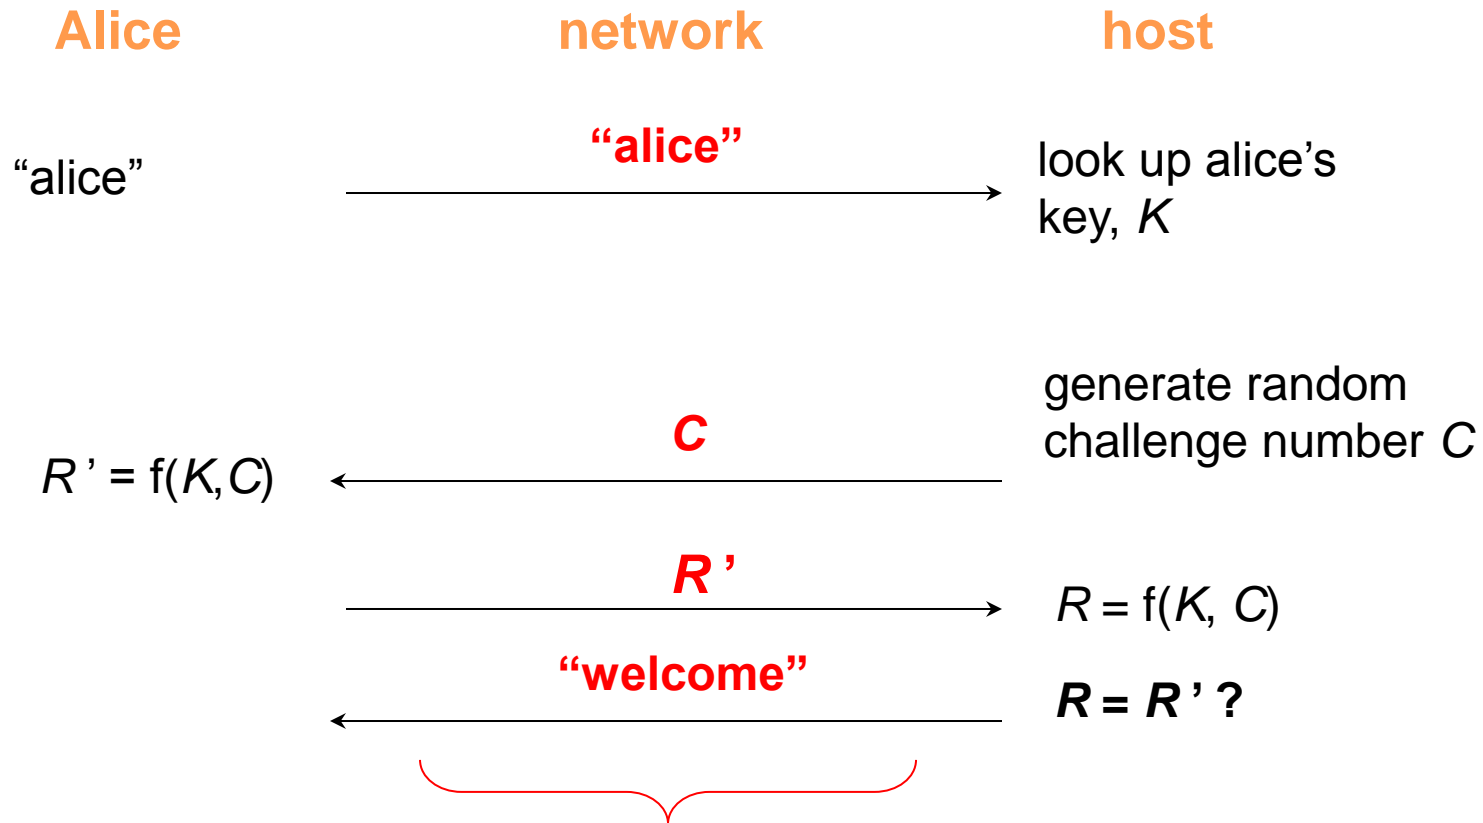

The challenge is a *nonce* (random bits).

We create a hash of the nonce and the secret.

An intruder does not have the secret and cannot do this!

# CHAP authentication

*an eavesdropper does not see  $K$*

# Man-in-the-Middle Attacks

- Password systems are vulnerable to **man-in-the-middle attacks**
- Attacker acts as application server

# Man-in-the-Middle Attacks

- Password systems are vulnerable to **man-in-the-middle attacks**
- Attacker acts as application server

# Man-in-the-Middle Attacks

- Password systems are vulnerable to **man-in-the-middle attacks**
- Attacker acts as application server

# Man-in-the-Middle Attacks

Password systems are vulnerable to **man-in-the-middle attacks**

- Attacker acts as application server

# Man-in-the-Middle Attacks

Password systems are vulnerable to **man-in-the-middle attacks**

- Attacker acts as application server

# Man-in-the-Middle Attacks

Password systems are vulnerable to **man-in-the-middle attacks**

- Attacker acts as application server

# Guarding against man-in-the-middle

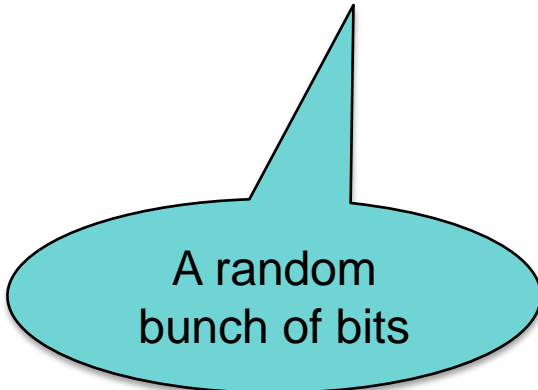

- Use a covert communication channel
  - The intruder won't have the key
  - Can't see the contents of any messages
  - But you can't send the key over that channel!
- Use signed messages
  - Both parties can reject unauthenticated messages
  - The intruder cannot modify the messages
    - Signatures will fail (need to encrypt the hash)

# Public key authentication

Demonstrate we can encrypt or decrypt a *nonce*

- Alice wants to authenticate herself to Bob:
- Bob: generates nonce,  $S$ 
  - Sends it to Alice
- Alice: encrypts  $S$  with her private key (signs it)
  - Sends result to Bob

A random  
bunch of bits

# Public key authentication

Bob:

1. Look up Alice's public key
2. Decrypt the message from Alice using Alice's public key
3. If the result is  $S$ , then Bob is convinced he's talking with Alice

For **mutual authentication**, Alice has to present Bob with a nonce that Bob will encrypt with his private key and return

# Public key authentication

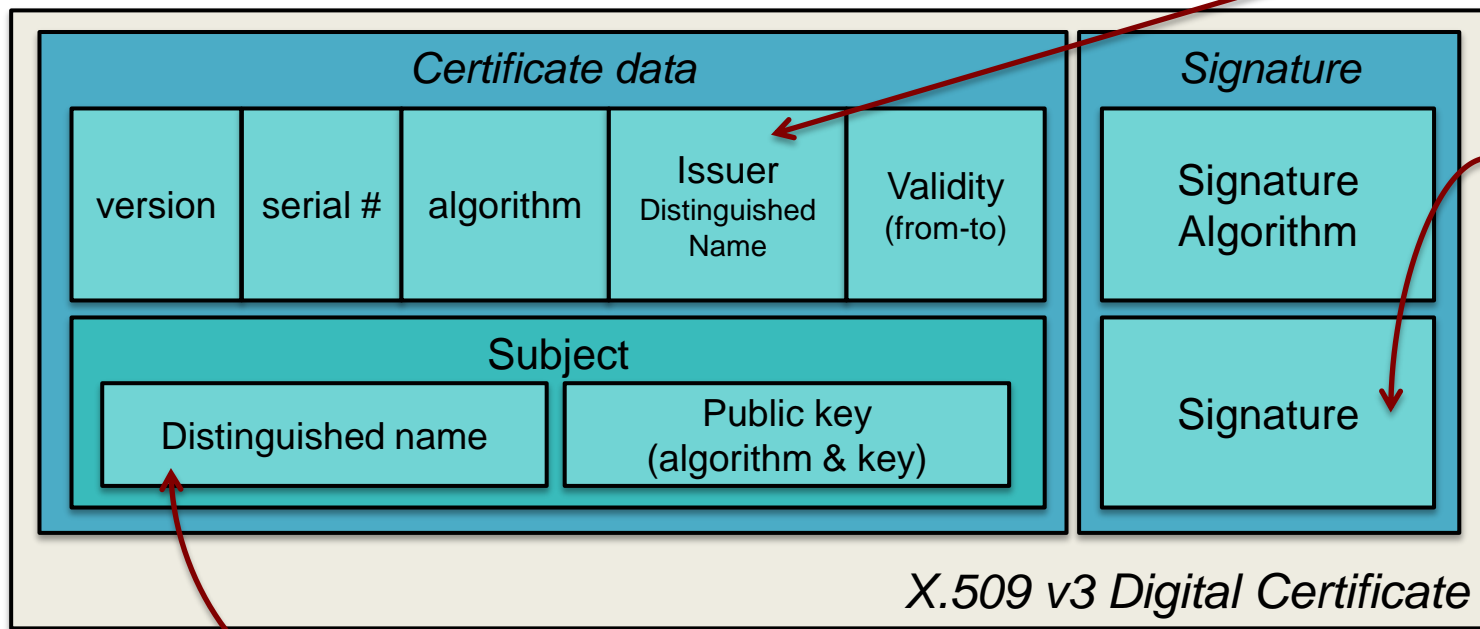

- Public key authentication relies on binding identity to a public key
  - *How do you know it really is Alice's public key?*
- One option:
  - get keys from a trusted source
- Problem: requires always going to the source
  - cannot pass keys around
- Another option: sign the public key
  - Contents cannot be modified without detection
  - **digital certificate**

# X.509 Certificates

ISO introduced a set of authentication protocols

X.509: Structure for public key certificates:

Issuer = Certification Authority (CA)

*Name, organization, locality, state, country, etc.*

# Reminder: What's a digital signature?

Hash of a message encrypted with the signer's private key

# X.509 certificates

## When you get a certificate

- Verify its signature:
  - hash contents of certificate data
  - Decrypt CA's signature with CA's public key

## Obtain CA's public key (certificate) from trusted source

- Certification authorities are organized in a hierarchy
- A CA certificate may be signed by a CA above it
  - **Certificate chaining**

**Certificates prevent someone from using a phony public key to masquerade as another person**

*...if you trust the CA*

# Built-in trusted root certificates in iOS 8
